

digital transmission systems that carry IP packets, can be traced back to this.

Generally, PSTN refers to the combination of lines and switches that form a system of electrical routes through the network. But before exploring the network, be clear with the basics of a telephone—both the equipment and signals. Look at the essential components of your simple age-old telephone set: ringer circuit, on-/off-hook circuit, equaliser circuit, hybrid network, speaker, microphone and dialing circuit; any advanced telecom equipment is built on the same scheme. Other network equipment like station equipment, local loops, trunk circuits and exchanges also need your attention.

In networking, you should know how a central office provides PSTN connection to the customer premise equipment (CPE). A CPE may be an individual phone at a residence or at a private branch exchange (PBX). However, nowadays, electronic PBX (EPBX)

are more popular than PBX. You are expected to understand the switching concepts: circuit switching and packet switching. For example, how circuit switching is used for making a standard telephone call on the public telephone network. In fact, circuit switching establishes a dedicated connection between the base and mobile for the entire duration of a call. But in a packet switching operation, single node-to-node link can be dynamically shared by many packets over time, so line efficiency is greater. Here mobile packet data connectivity systems like cellular digital packet data, RAM mobile data and advanced radio data information systems are important to understand.

Bear in mind that any network needs a system to control its traffic. The signaling system is the controlling factor. You need to understand how the common channel signaling systems control telecom traffic. You may even put a special emphasis on the global

standards like Common Channel Signaling System No. 7 (SS7 or C7).

Today, SS7 is being used throughout by the Bell Operating Company's telephone network and most of the independent telephone companies because it has the ability to transfer all types of digital information as well as support most of the new features and applications involved in advanced networks like integrated services digital network (ISDN) and interfaces like asynchronous transfer mode (ATM). Understanding of the network transmission hierarchy may prove useful.

How is telephony designed?

Let's start with the traditional landline telephone system POTS. It handles both signaling and audio information on the same twisted pair of insulated wires: the telephone line. The signaling equipment consists of a bell, beeper, light or other devices to alert the user of incoming calls, and number buttons
