

Access to local customers driven by domestic consumption will enhance product knowledge and further catalyse maturation of the Indian companies to be able to do complete product development.

—Praveen K. Ganapathy, director-DSP business development, Texas Instruments India

low power consumption.

At system-level trend could be towards "More than Moore" (integration of diverse and unrelated technologies like silicon VLSI, biosensors, high-power components and MEMS in a single system-in-package) rather than "More of Moore" (integration of more and more transistors on a single silicon system-on-chip and operating at higher frequency).

Digital security and surveillance is one of the hottest applications in the embedded arena benefiting from the multicore phenomena. Old surveillance systems requiring human monitoring are rapidly being replaced with intelligent surveillance systems. Also, the latest security and surveillance solutions need to be able to capture and process security video in real time.

"New applications would be e-passports, smartcard-based rural banking and micro-finance, live-stock identification and identification-based vehicle security," says Dr N.S. Murthy, director, new business initiatives, NXP Semiconductors.

High-end designs churned out of India

Poomima Shenoy, president of India Semiconductor Association (ISA), says that most (if not all) of the companies are responsible for some design blocks. And, these blocks will need to, more often than not, be used in more

than one design of that company, at the global level. This means that in addition to just developing a block, the local design team should make it a fully packaged, independently usable block, *a.k.a.*, intellectual property (IP). Also, as complete products are increasingly being developed in India, they are also responsible for their 'IP packaging.'

Some of the technologies (IP) championed from India include:

1. OMAP from TI
2. Sharkfin from ADI
3. Wireless IPs from Ittiam and Wipro

4. Communication interfaces, like Bluetooth, from MindTree

TI's scalable OMAP35x portfolio of devices is available for manufacturers wanting to redefine the standard for advanced user interfaces, Web browsing, productivity and multimedia experience, making it easier than ever to access information and media.

Target applications of OMAP devices include portable navigation devices, point-of-sale systems, patient monitoring and other medical applications, software-defined radio, IP-based communications, smart home media controllers, edutainment (eDictionaries) and portable consumer entertainment devices like portable media players and portable TV sets.

Freescale India design centre has completed many designs in the domains of wireless, networking and
