

Motorola Motozone

1. Taking good-quality photos
2. Printing the photos
3. Storing a reasonable number of photos

In order to meet these requirements, the camera phone should have the following features: good resolution, Bluetooth, memory card, PictBridge and carrier network. Also features like video conferencing, Internet browsing with HTML, 3G and e-mail application along with some advanced features like GPS navigation and Internet on WLAN may be taken care of while buying a camera phone.

Touch screen has not only made the working easier for the users but it has also added to the style statement for the youth as well as for the elite class for buying a mobile phone. But of course, before you plunge into buying any cellphone, think about why you need it, how you will use it and what

your budget is.

Camera essentials

With the evolving consumer needs, more and more phones are being introduced with camera resolutions ranging from VGA and more. However, most camera phones do not have such features as optical zoom, auto focus and built-in flash that are common in digital cameras. There are high-end camera phones that have these features, but keep in mind that you may have to sacrifice size and battery life to get these features.

Resolution. The constant climb of megapixels in camera phones is threatening the digicam market, which boasts 10 megapixels at high-end. With support for 5 to 8 megapixel resolution, cellphones have cameras of almost equal resolution as compared to the current-day digicams.

Recently, LG had refreshed its portfolio with an 8-megapixel camera phone. After 5-megapixel Omnia, Samsung too has launched an 8-megapixel camera phone, Innov8, designed for mobile photography in the Indian market. Sony Ericsson already has an 8.1-megapixel C905, which comes with Xenon flash, face detection and auto-focus.

Keep in mind that VGA (640×480) quality will not be good enough for photo-quality prints. 1.3-megapixel cameras may sometimes produce an acceptable quality, but generally they may not. Printing a good-quality photo

on a 10×15cm² paper requires at least a 2-megapixel camera phone. There are lots of phones available with 2MP camera. Higher resolution is better for producing more detailed photos or larger prints.

Lens. The quality of the lens represents the overall quality of your phone's camera. Carl Zeiss lens takes exceptional photos considering the limitations of such a small device. Also, Schneider-Kreuznach have developed a reasonably good lens system, but there is a considerable difference in the performance of this lens as compared to the Carl Zeiss lens.

Flash. Considering the simplicity of the lens structure in a camera phone, the image sensor needs all the help it can get to achieve a decent exposure. A flash is an absolute must, but surprisingly many camera phones are still lacking it. There are currently two options available to better light your subjects: LED and xenon. Also known as a strobe flash, a xenon flash emits an extremely bright burst of light and is the flash of choice for camera phones.

Zoom. Basically, there are two types of zoom: optical and digital. Many manufacturers will try to sell their models on the basis of digital zoom. However, you should know that digital zoom gives you larger image compromising the quality. Go with the optical zoom as you can get enlarged pictures with good quality.

Optical uses adjustments in the distances between the elements in the lens
