of green production is to minimise emissions and e-wastes; minimise the use of virgin material and non-renewable forms of energy; and reduce the lifecycle cost of products or services," says Tiwari.

The Indian government is taking the initiative to market Indian manufacturing as green to make it popular and have an edge over Chinese or US products which are typically energy-intensive. According to the government, Indian manufacturers in most sectors are far more energy efficient than their counterparts abroad. Their manufacturing processes and products are more environmentally compatible.

India's per capita greenhouse gas emissions is slated to increase threefold by 2030 and is set to reach up to 7.3 billion tonnes of carbon dioxide by 2031. This alarming trend is partly due to the Indian IT industry. According to IDC, the energy emitted by desktops and laptops alone contributes to enormous levels of greenhouse gas emissions as a large amount of the power in desktop PCs is wasted as heat. "Next to the US, Russia and China, India is proclaimed as the world's fourth-largest polluter. Hence the need of the hour is to invest

in green and clean technologies in our country. India must start looking at developing technologies that will abet the green movement and the government is willing to invest in driving this mission," states Tyagi. "While there is support from the government, the industry too needs to collaborate by not just developing green technologies

but also ensuring its implementation," he adds.

Green gadgets

Indian biggies have started taking the initiative, though in baby steps. Many firms are going in for 'green technologies'—from techniques to generate energy to non-toxic cleaning products. Some companies are interested in technologies that eliminate lead; some others go in for those that recover material from the product during processing. In the automotive industry, the focus is on technology that can reduce emissions and recover materials that improve conservation efforts.

To comply with social responsibility and profitability factors, companies are also developing electronics components and systems that are very low on electricity consumption and are aptly called energy-saving gadgets. This is despite the fact that the production of energy-efficient appliances is nearly 5-15 per cent costlier.

Encouraged by the success of energy-efficient ACs and refrigerators, consumer electronics companies are now making TVs, washing machines and microwave ovens green as well.
