

"LG's star-rated colour televisions comply with the guidelines issued by the Bureau of Energy Efficiency (BEE) for annual power consumption. LG's five-star rated televisions have an APC of 147 kWh/year in the 53cm models and 204 kWh/year in the 74cm model (considering a daily usage pattern of six hours in 'on' mode and 12 hours in 'standby' mode). These star-rated TVs result in energy savings of up to 50 per cent on an annual basis," says Tiwari. "LG's star-rated air-conditioners and refrigerators have also received the coveted star-rating from BEE. The secret lies in our extra powerful compressor and our design for the evaporator/condenser coils. These optimise every bit of power to give maximum efficiency and cooling and cuts down the electricity bill," he adds.

"LG's LCD and plasma TVs can be considered green due to the use of different permutations and combinations of energy-saving modules, intelligent sensors, video mute and zero wattage used in standby mode, all of which help in saving energy. LG has provided a one-touch remote key for activating the energy-saving mode in all its recent LCD and plasma models. Our CRT TVs are also green as they use energy-efficient power supply circuits and less than 1W used in standby mode that saves energy," adds Tiwari.

LG plans to launch more energy-saving gadgets in the future as well. "We would like to introduce the energy-saving mode to all our product lines. For example, we have recently introduced star-rating in our new range of CTVs. Globally, LG runs a 'green product' campaign for LCD and PDP TVs which not only focuses on en-

LG refrigerator

ergy-efficient products but also products complying with RoHS norms," he says.

BenQ also claims to produce green products. Each of BenQ's products have at least three eco-labels. "The green factors are taken care of at the design stage—BenQ products use 28 per cent recycled plastic material and 70 per cent recycled paper. Its products save electricity by 30-40 per cent," says the BenQ spokesperson. "Some of our green gadgets are LED monitors—V2400 and V2200—followed by products in Joybook, the LCD TV VK3211,

the projector MP772ST, the all-in-one PC i221Eco, etc," he adds.

Freescall Semiconductor India provides chips that play a big role in saving energy in customers' end products, claims the company. "We work with our customers and business partners on developing new techniques for next-generation products that are more energy efficient. Whether the application requires a longer battery life or needs to reduce heat dissipation, the system designers have to rely on semiconductors that meet their performance requirements without exceeding a limited energy budget," explains Tyagi.

Freescall works closely with its customers to clearly define the performance and energy parameters they require. "Through close cooperation, we can optimise our solutions to help them make energy-efficient designs that are easy to develop, speed up the time to market and are more attractive to customers," he adds.

Remanufacturing and recycling

Green manufacturing also involves product recovery

activities and reverse logistics. Product recovery activities are undertaken to convert a returned product into a usable one through various activities like remanufacturing, recycling, refurbishing, etc. Reverse logistics focuses on the inbound supply and distribution of used products and inventory management.

While recycling is done to recover useful material, remanufacturing is done for the recovery of parts, components and modules. "These recovered parts or components are cleaned, inspected, sometimes tested and, if
