

MIT researchers are developing extra robot limbs that can help out humans where an extra hand, arm, or leg might be useful (Courtesy: <http://www.gizmag.com>)

enables the user to grab or hold different objects firmly. It learns the natural movement of hand and performs tasks without any extra command. The robot is designed to learn the natural movements of fingers.

The device has actuators in it, which are linked together to apply force. These actuators create same strength as that of human fingers. This robot has multiple position-recording sensors. Researchers have developed the control algorithm of robot on theory basis of bio-mechanical synergy. Recordings collected from sensors are used to optimise the algorithm in order to assume certain posture of hand.

Smart seats to alert sleepy car drivers

Number of car accidents is rising rapidly in most countries. Most of these accidents happen due to drivers' negligence; they tend to lose their alertness due to dizziness they feel while driving. Researchers from Nottingham Trent University have developed smart seats for cars with the help of a firm named Plessey. These seats alert the driver when he or she starts falling asleep. Researchers have used ECG sensors in seats. These sensors detect driver's heart rate and detect if the driver is falling asleep due to fatigue.

The team is planning to implement fabric-based sensors in seats, which can send a warning message to drivers and ask them to pull over. The system can also trigger car's cruise control or lane departure technology, if driver ignores the warning. Using wireless network, the sensors can send information to nearby traffic control centre.

Smartphone to analyse your DNA

Researchers from Polytechnique Montreal and Gorilla Glass manufacturer Corning are attempting to achieve something very useful for any forensic expert. They are developing display sensors for smartphones which can use user's spit to not only detect the body temperature but also analyse his DNA. The researchers claim that sensors can be embedded inside the smartphone's display, which will allow users to check their body temperature, help diabetic patients to check their blood sugar levels and work with platforms like Apple's Homekit to give detailed report on user's health.
