city, which has a large number of commercial buildings and other important establishments and tourist centres like BSE building, Hotel Taj Mahal and Chhatrapati Shivaji Terminus. A

because one would know of any incremental RF emission as soon as it happens.

The process of installation and commission of sensor-based systems

typical deployment and control scheme for Mumbai city is shown in Fig. 5, where RF sensors are located at strategic locations and their time-stamped data is pulled at NOC for network view of RF operations in the city. This is a true proactive monitoring

remains the same as explained in Fig. 4. For better insight of the entire city, drive test with data recording facility can supplement areas in which the RF sensors cannot be easily deployed. The drive data and the stationary sensor data can be correlated at NOC and emitters can be determined.

Coastal/border surveillance

The third and final example is of very large-scale monitoring, which can be coastal or border surveillance systems. The system works on the same philosophy as described in previous section, with a difference that the RF sensors are located along the coast or border, and that the granularity of deployment is not as dense as in previous case. The deployment locations can be hill-top or resorts where uninterrupted data connectivity to NOC is available.

These systems also work 24x7 for continuous signal monitoring and analysis. The operational activities of this coastal/border application are the same as in Fig. 5, where the surveillance systems along the coastal or border area, with suitable backhaul connectivity, can cover the entire sensitive border area. Fig. 6 is an indicative example of such deployment. ●

The author is application engineer in Electronic and Measurement group of Agilent Technologies at Hyderabad. Along with Master of Engineering degree and specialisation in systems and signal processing, he has over 12-year experience in RF surveillance and communication, EW systems development, integration and testing
