till recently

Today's start-ups and greenfield offices require phone systems, data routers, wireless access points, LAN, fixed cellular terminals and voice gateways. NAVAN CNX200 is a converged voice and data platform for small set-ups and branch offices with up to 24 IP users. It helps to get rid of buying and maintaining separate devices for office communication.

NAVAN also helps cut down costs associated with multiple repairs, annual maintenance costs and pay checks of voice and IT staff to maintain day-to-day business communication. Advanced features of NAVAN CNX200 provide customers with big-business capabilities, boost staff productivity and enhance collaboration with customers and suppliers.

NAVAN has built-in IP-PBX, integrated data router, eight-port network switch, Wi-Fi access point, IPsec/SSL virtual private networking (VPN), firewall, policy based access and mobility features. Easy-to-use-and-manage, NAVAN reduces the overhead of skilled manpower, simplifies infrastructure by cutting cords and saves space and energy costs.

NAVAN offers more than just the sum of different devices working in silos. It scores high compared to stand-alone IP-PBXes and routers sold in the market. Besides, it offers advanced features, such as multi wide

area network (WAN), VPN, e-mail to SMS, computer telephony integration (CTI) and specialised Android/iPhone softphone with unified-communication features.

Another unique aspect is its price, as NAVAN costs 30 per cent or lesser as compared to the individual devices put together. Integration of its all-in-one functionality eliminates rat's nest infrastructure as NAVAN works on the same data networks in the office. With easy-to-manage settings, NAVAN saves money by eliminating the need of skilled manpower to manage voice and data set-up in the office.

Integrated design

NAVAN is a unique blend of diverse technologies. Let us take a brief look at what made the integration in NAVAN possible.

Multi-layer PCB approach. Matrix NAVAN uses a six-layer PCB design, making it ideal for a multi-tasking device, while maintaining reliability. Conventionally, products with similar functionality make use of a single- or dual-layer PCB for saving cost. This makes those products bulky, non-reliable and prone to more downtime. Multi-layer PCB approach used in Matrix NAVAN enhances high-speed circuit operations, provides more space for semiconductors and consumes less power to support Green IT approach.

Distributed processing architecture. Matrix NAVAN is an integration of various technologies, such as VoIP, GSM, UMTS/HSPA, wireless LAN and TDM. In the distributed processing architecture used in NAVAN, each processing module handles only specific tasks to achieve the highest level of reliability. For instance, different processors are used for major modules like VoIP, network, etc. All interfaces of the product are employed in one common platform. This helps NAVAN achieve its core objective, an all-in-one platform. All chips and interface
