

Design Suite revolutionises wireless prototyping for software-defined radio

NTI, the provider of solutions that enable engineers and scientists to solve the world's greatest engineering challenges, has announced LabVIEW Communications System Design Suite, which combines software-defined radio (SDR) hardware with a comprehensive software design flow to help engineers prototype 5G systems.

Wireless prototyping was previously undertaken by different design teams using disparate design tools. The LabVIEW Communications environment enables the entire design team to map an idea from algorithm to field-programmable gate array (FPGA) using a single high-level representation. This approach empowers designers to

LabVIEW tuned-in to a software-defined radio

focus on innovation instead of implementation, which increases the rate and quality of their prototyping.

LabVIEW Communications is optimised for an SDR platform with a hardware-aware design environment that provides control of physical configuration, hardware constraints and system documentation in a functional software diagram. This adds flexibility of the hardware to the software, which gives designers access to all components in the SDR platform. This solution helps designers achieve optimal performance by eliminating the need to manually map algorithms to different hardware architectures.

World's fastest camera can capture 100 billion frames per second

The fastest camera in the world, which can capture events up to 100 billion frames per second, has been successfully developed by a team of biomedical engineers at Washington University. Current imaging techniques allow only on-chip storage and operations of about 10 million frames per second.

Researchers have claimed that it is the fastest 2D receive-only camera that uses a technique called compressed ultra-fast photography. This technique improves the imaging frame rate by magnitude and will result in a new regime of visions. An array of devices is included in this technology, like microscopes and telescopes, which get paired with lenses to capture events.

Now BINAY Circadian PowerLED Lights Can Make You Healthy

BINAY kelvin-changing Human-Centric Circadian PowerLED Lights are designed to affect the human circadian rhythm positively for enhanced physical and mental well being

BINAY has developed kelvin-changing Human-Centric Circadian PowerLED light fittings which have colour temperature changing properties. The colour temperature of the light emitted by these fittings can be manually changed as desired, or set to change according to a pre-set programme. These lights affect the body clock in the human body positively, encouraging the release of appropriate hormones depending on the time of the day (thus leading to increased alertness and productivity during daytime, and improved mental and physical relaxation in the evening).

Greatest importance for applications in:

- **Workplaces such as office and factories**
(for enhanced productivity and improved alertness)
- **Healthcare facilities such as hospitals and nursing homes**
(to facilitate patient recovery)
- **Educational applications such as school and colleges**
(where enhanced mental concentration is required)
- **Residential applications**
(alert and productive cool daylight during the day, and restful warm white in the evening)
