

play module to your Raspberry Pi or Arduino-compatible board.

If you are working with E-Ink displays, there are easy-to-use PC USB powered kits based on open source software and tools. The latest EPD kits include pre-loaded firmware to take data via USB that are later sent over to the extension boards.

Future: LED displays with high resolution

When we talk of LED displays, these are not true LEDs. These are LCD displays with LED backlights. Nate Srinath says, "Till date we haven't perfected an LED display with very high resolution."

We can increase features in TFT-LCD technology and make power-efficient designs, but we have to look for advancements in greener technologies like LED and OLED for the future. Previously it was possible to make only small OLED displays, but over time manufacturers have started making the process more efficient. They are now able to make larger

displays, but still the cost-efficient yield of OLEDs has to be achieved.

Experts believe that true LED displays with high resolution can be more power-efficient with a high contrast and brightness coming as natural features. However, can we actually have high resolutions with true LED displays?

Nate Srinath, founder-director, Inxee says, "It is possible with manufacturing capability changes. Today we can't manufacture an LED lamp smaller than a particular dimension. So we have to improve upon that and

make smaller and smaller LEDs to hit extremely minute dimensions and be able to control them individually with good spectral characteristics. This will eventually lead to displays that will be very rugged and extremely modular. You can build your own giant flat-screen TV using smaller modules. Even if you throw water or stones on them, or break a pixel, it will continue to operate. Maybe 4-5 years down the road, we will be able to see such displays." ●
