There are some that are not very friendly with third-party applications. Android being an Open platform, supports many applications and hence the 'in and it' among the pack.

However, if a particular application is made for a particular tablet, it is meant to work best at the known screen size and resolution of that tablet. Android applications work across multiple screen sizes, which might not give a very good tablet experience.

Processor. It defines the processing speed of various functions and applications that the tablet performs.

Screen size. "Size does matter" could be a misnomer with tablets. Tablets come in different screen sizes. However, screen size on paper might be very different from the actual look. A 17.8cm (7-inch) screen in sight looks almost half the size of a 25.4cm (10-inch) tablet. A bigger-screen tablet with its adequate keyboard dimensions will make data input a better experience. Adding onto it is lesser sustenance on the zoom option. Not to mention that the visual treat is kinder to your retinas, and creating and editing documents easier.

However, in terms of portability, these fare poorer than smaller-screen tablets. Smaller-screen tablets are lighter, handy, slip easily into the pocket and exemplify the designed utility of a tablet! However, smaller size typically means decreased battery capacity too. Also, tablets with 12.7 cm (5-inch) or smaller screen sizes are almost like a big-screen smartphone only.

Resolution. Resolution affects the visual treatment that a tablet offers. Media playback and Web browsing experience hinges on the screen resolution factor and therefore the resolution matters (refer Fig. 1 for an overview of the difference in screen size made by increase in resolution). Many seldom understand the meaning of resolution in terms of practical limitations and how it corresponds to software availability and physical screen size. The difference in resolution affects how much you actually see on the screen.
