

Where Passive Components are Headed

While India manufactures and exports resistors, capacitors and wound components, there is almost negligible manufacturing happening for crystal oscillators and piezoelectric crystals. Developing the required raw materials base within the country will help it push Indian manufacturers to do value addition and make other components as well

UMA GUPTA

The growth of the electronics industry in India has triggered the expansion of electronic components manufacturing as well. At present, there are around 1600 electronic component manufacturers in India. Passive components account for a major chunk (20 per cent) of the total electronic components market. Wound components contribute about 80 per cent of the total passive components market followed by capacitors.

The demand for passive components is met through indigenous manufacturing (34 per cent) as well as imports (66 per cent). It's mainly small-scale industrial units that manufacture passive components in India.

Among passive components, the share of indigenous production for wound components is relatively high, with close to 30 per cent being produced in India. However, components like resistors and capacitors continue to be imported in big proportion.

The fact that India is not the home to large-scale manufacturing operations for consumer electronics products like China works against components manufacture here.
