

Car of the future

Visteon recently showed off e-Bee—a concept car created using a Nissan Leaf. It has all the automotive electronics you want to see in your car in the future – and if Visteon's estimate is right, your car might look pretty much like this by 2020. It has everything from entertainment and mobility solutions to safety and comfort.

Inside: Boxes and boxes of electronics, including personalised HMI, touchscreen instrument panels that give information on vehicle controls and social media connections, a head-down projected main display in front of the driver, a rear view with 360-degree visibility and augmented reality features, tech-agnostic wireless charging, Open Source infotainment platform, near-field communications for personal link between the user and vehicle, climate control system, cloud connectivity and car-to-car communications for improved information about collisions, hazardous roads, curve speed warnings, traffic flow and more. Most of the technology is based on an open platform.

A mouse that fits any palm

BMW Design Works and Thermaltake have together launched the Thermaltake Tt eSports Level 10 M gaming mouse, which can apparently be adjusted to fit to any palm size. It also includes several ergonomic features including a palm-cooling design.

Inside: The mouse features a hollowed-out design that allows height and angle adjustment of the mouse body by simple turning of a screen on the top side of the mouse. A perforated palm surface, advanced materials and unique shape manage to maintain a passive airflow that removes sweat from the palms. The mouse works using a laser sensor with a sensitivity of 8200 dpi, 128kB memory, LED lighting and USB connectivity. It comes bundled with the requisite software.

Cubical display for an immersive experience

Samsung's NL22B is a cube-shaped device that contains a transparent 56cm (22-inch) front-panel display with a computer built into the chassis. It allows images and animations to interact with the products showcased inside the cube. Apart from creating an immersive shopping experience, it could also be used in fields like education and healthcare. It might, for example, be used in a store to allow users to interactively find out more about products and try out various combinations, before making a purchase.

Inside: 60Hz transparent LED display, protective glass, speakers, security lock and cables, USB input and Ethernet connectivity. Built-in AMD A4-3310M dual-core processor allows users to easily control the display, without the need for external PC. Embedded MagicInfo Premium software enables images or videos to be played from a USB source, or deployed and managed from anywhere in the world using a network.
