

Mixed-Signal MCU with DSP and FPU Cortex-M4 core with a rich analog peripheral set

STM32 F3

Get 43% more performance for critical routines using CCM-SRAM

With the STM32 F3 series, STMicroelectronics innovates in embedded digital signal control (DSC) design by combining a Cortex-M4 core with rich analog peripheral set plus core coupled memory (CCM-SRAM) to optimize code execution time. Critical routines loaded in the safe 8-Kbyte CCM-SRAM at startup can be completed at full speed with zero wait states, achieving 90 Dhrystone MIPS at 72 MHz. This compares with 63 DMIPS when executing from Flash or SRAM; equivalent to a 43% performance increase for critical routines.
