

Acer Aspire AS5750z

playing older-generation games amidst listening to some music, a mid-level processor like a Pentium Dual Core or a Celeron Dual Core will serve the purpose.

On the other hand, scoring low on cost and power consumption, Intel's Atom processors run majority of the netbooks in the market. This processor is suitable only for those tasks which are light on resources, such as editing documents, working with emails, basic Internet browsing and accessing light multimedia resources. Running HD videos or playing heavy video games may deliver sluggish performance.

But over the years, the Intel Atom processor family has underwent several enhancements. The latest processor in the Atom hierarchy chain is the Dual Core Second Generation, which is pretty fast than its predecessors. A similar enhancement trend can be observed in the Core i3, Celeron Dual Core and Pentium Dual Core families, which have been upgraded to the second generation.

Graphics

Though a high-end CPU is very powerful in itself, it may still not guarantee the graphics experience that you have

always dreamt of. All laptops come preloaded with at least an integrated graphics processor (IGP). The IGP shares the video memory with the system memory.

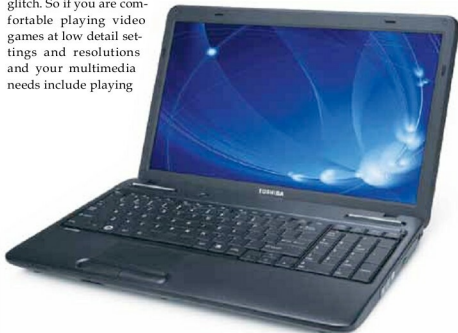

A few years ago, IGP's delivered awful results in playing heavy multimedia applications, which is not the case now. These days, IGP's can handle entry-level 3D gaming and play any HD video without any glitch. So if you are comfortable playing video games at low detail settings and resolutions and your multimedia needs include playing

HD movies and basic editing tasks, an IGP would suffice. In the budget price segment, an IGP would offer you video memory of 64 MB, 128 MB or 256 MB.

However, if you are ditching your powerful desktop for a laptop, only to add mobility to your extreme gaming needs, look for a dedicated graphics processing unit (GPU) in your laptop. Contrary to an IGP, a GPU has its own individual memory. For resource-intensive tasks like heavy video editing and playing high-end video games, it is advisable to buy a laptop with its own GPU. A video memory of 512 MB and above is what you will find across several GPU-embedded laptops. But alongside delivering crisp and crystal-clear graphics, a GPU can severely impact battery life and burn a hole in your pocket.

RAM

The RAM acts as a temporary storehouse for all the programs that you run on the laptop. It comes in various types like DDR, DDR2 and DDR3, the latter being the fastest and the most expensive. While Windows 7 has become the de-facto
