

Battery that recharges in 10 minutes

Say hello to the next-generation lithium-ion battery which can be recharged within ten minutes! Researchers at the University of Southern California (USC) Viterbi School of Engineering claim that the new batteries hold three as much energy as its existing counterparts.

The new batteries could be used in anything from cellphones to hybrid cars. The design, currently under a provisional patent, could be commercially available within two to three years. "It's an exciting research. It opens the door for the design of the next-generation lithium-ion batteries," said Chongwu Zhou, professor at the USC Viterbi School of Engineering, who led the team that developed the battery.

Bracelet that connects to Android smartphone

Technology knows no bounds! For all the Android smartphone lovers who want to avoid carrying their huge devices in their hands, here is a bracelet that will keep you connected to your smartphones without the burden of carrying one.

Embrace plus allows users to set notifications for incoming calls, text messages, Instagram, email, Twitter, Facebook, Tumblr, LinkedIn, Skype, Calendar Alerts and much more. The bracelet can be connected to any Android smartphone running Android 2.3 and above.

A novel sensor

Engineers at the Duke University have come up with a novel sensor that is said to be more efficient and cheaper for potential use in airport security scanners, and collision avoidance systems for aircraft, cars or maritime vessels.

The researchers fabricated a unique material, known as a metamaterial, that acts as a lens to image scenes using fewer components than conventional detectors. Because of the properties of this man-made material, much of the additional equipment needed for conventional detector systems—like lenses, mechanical

positioners, and data storage or transmission devices—are not required.

The new system works with microwave light and produces two-dimensional images.

India-based firm designs smallest Android smart watch

Samsung belongs to Korea, HTC is located in Taiwan, Sony is a Japan-based brand and even Micromax sources its products from China. But amongst all these biggies, an India-based tech firm, called Android Systems Pvt Ltd. has launched the smallest Android-based watch that comes with smartphone-like features.

The company has priced the innovative miniature device, starting at \$249. This smartwatch sports a 5cm (2-inch) display and runs Android 2.2 aka Froyo. The watch is powered by a 416MHz processor and 256MB RAM. It also comes with a camera, Wi-Fi and Bluetooth support, SIM card slot, Google Play Store and other wireless

achieved without tethering or burdening users with 3D glasses.

Nano technology to double HDD density

HGST (formerly Hitachi Global Storage Technologies) is leading the disk drive industry to the forefront in nanolithography by creating and replicating minute features that will allow the doubling of hard disk drive (HDD) density in future disk drives.

HGST Labs announced that they have combined two innovative nanotechnologies—self-assembling molecules and nanoimprinting—to create large areas of dense patterns of magnetic islands only 10 billionths of a meter (10 nanometers) wide. These features are only about 50 atoms wide and some 100,000 times thinner than a human hair.

Here comes brain painting

Imagine this. You can draw a painting using the power of your brain, without having to move your hands. Well, sounds like a scene of a sci-fi thriller! At CeBIT this year, it actually turned into reality and attracted a huge crowd. As part of the intelliX system, which is pioneered by Austrian firm g-tec, a user can wear a cap that measures brain activity.

The system is basically a computer program that can help paralysed patients draw artworks simply by using the power of their brains. The way it works is that the user wearing the cap has to focus hard on a flashing icon on a screen, which then maps brain activity connected to that item, thereby allowing them to guide the computer on what they want to do. In total, the solution costs \$15,000, which includes the brainwave-reading cap, the computer software and the technology to interpret the brain activity.

Transparent phone prototype is here

Ever fancied having a transparent mobile phone, a device you can look

Brain painting

modes. The watch also has an internal storage capacity of 8 GB.

A 3D see-through computer

A transparent 3D computer was recently unveiled at the Technology, Entertainment and Design (TED) 2013 conference in California. Developed by Jinha Lee—a graduate student at MIT, the SpaceTop 3D desktop has the potential to radically alter the way we interact with personal technology. The device works via a combination of a transparent display and 3D gesture detection algorithms that are placed in the input space. 3D rendering, as per Lee, is
