

Biometrics: Concepts and Applications

The main purpose of the book is to address various challenges in different biometric systems. It discusses about the different types of biometric modalities, such as face, irises, retina, fingerprints, etc, and provides an overview of various biometric security technologies along with their scope of implementation as well as advantages and disadvantages. The author has also given a direction for using suitable soft computing techniques or tools.

The readers of the book will have an exposure to the theoretical concepts of biometrics as well as their applications and scope of implementation.

It is a useful text book for undergraduate and post-graduate students pursuing courses in computer science engineering, electronics and telecommunication engineering, information technology and other applied disciplines. It will also be helpful to researchers and scientists working in the field of digital image processing, particularly biometrics.

Theory of Computation

In the book, the author has made an attempt to deal with the complex concepts of computation theories from an engineer's perspective.

It can serve as a textbook for students pursuing undergraduate courses in computer science and engineering, and information technology.

The emphasis of the text is on concepts, such as automata theory, regular expressions and Turing theory. This is further supported by working examples that provide knowledge about the practical applications of each of the topics. The text also contains plenty of objective type questions and review questions for practice.

It also deals with the theories related to the practical aspects of computation—problem solvability, program verification and algorithmic solutions. However, the book is not suitable for starters as the author has assumed that the reader already has some exposure to the concepts of data structures and algorithms.
