

said Radcliffe to the newspaper. A funnel, which is attached to the camera, is placed over the object or environment a person wishes to capture. After that a pump sucks the air across an odour trap made from tenax, which is a porous polymer resin that absorbs the particles that comprise the smell.

Dress that lights up if someone stares at it

Canada-based designer Ying Gao has created a unique dress that has beautiful patterns and light ups if someone stares at it.

"We use an eye-tracking system so the dresses move when a spectator is staring. (The system) can also turn off the lights, then the dresses illuminate," Gao was quoted as saying by *Dezeen* magazine. The eye-tracking technology embedded with the dress responds to an observer's fixed gaze and activates tiny motors that move parts of the dress in mesmerising patterns.

An all-optical transistor

With the recent invention of MIT engineers, electric power can be duly replaced by the power of light. They have succeeded in making a transistor that will use light instead of electricity for power and perform similar computing processes. This could be duly thought of as a switch that is turned active (on) by a single photon (light molecule).

According to the researchers, this breakthrough in the technology means that an entirely new platform for quantum and classical design could be achieved, and this will be able to operate at an exponentially faster speed than traditional computers.

15-year old Indian girl qualifies for finals of Google Science Fair

A 15-year old Mohali girl, Shristi Asthana, has qualified for the finals of Google Science Fair, 2013. She is also the only Indian student to reach this stage, according to a company statement. She had presented a project that deals with green technique for detergent degradation. Shristi will compete with 14 finalists at Google headquarters in the USA in September. The winner of the competition would be awarded with a 10-day National Geographic trip to the Galapagos Islands plus \$50,000 as scholarship.

Now you can charge inverters using the power of Sun

Tata Power Solar has come up with a retrofit unit called SunJeevini that allows charging conventional inverter batteries with solar units. For areas that are worst hit with long durations of power cuts, this could be a highly suitable alternative. In the absence of grid power supply, the existing inverters could as well be charged with solar energy and used in time of crisis. This also helps save on electricity bills.

Robot rockers play debut gig in Japan

Z-Machines, Japan's all-robot music band, recently made its live debut in Tokyo in front of curious onlookers. The robotic band, including a guitarist, a drummer and a keyboard player that can project laser beams from its eyes, was joined onstage by pop girl duo Amoyam. Around 100 people turned up in a popular Tokyo club to watch the social party robot band play its concert. Though details are scarce, these robots are reportedly powered by Android.

Raspberry Pi-powered robot that will make coffee for you

Scientists in Japan have developed a humanoid robot, Rapiro, which can be programmed to carry out various commands and would work like a personal assistant. The robot is the size of an average credit-card and works on Linux-based Raspberry Pi computing board. It is designed to work with the basic hardware of Rapiro and allows the user to program it to carry out various tasks including management of a personal calendar, keeping track of the weather and of course making coffee.

A bionic ear 'printed' in 3D

Scientists at the Princeton University, led by an Indian-origin researcher, have developed a 3D-printed 'bionic' ear which is capable of 'hearing' radio frequencies far beyond normal people's range. After the 3D printing of cells and nanoparticles, the researchers went for cell culture to combine a small coil antenna with cartilage to create the 'bionic' ear. In the long run such experiments could lead to the development of customised replacement parts for the human body.

Chip that will detect blood drop for diseases

Scientists from New Jersey have come up with an exciting new invention — a cutting-edge chip that can sense diseases from a blood drop. According to the new study, Alokik Kanwal and Reginald Farrow, both researchers from the New Jersey Institute of Technology, have come up with a carbon nano tube that would quickly detect mobile cells.

The team members believe that this device would perform non-invasively and will help detect high degree of spatial concentration within no time. For medical professionals, this would be a

handy device to measure the electrical properties of blood drop of patients and check for diseases, *Science Daily* reported.
