

A virtual child to identify paedophiles worldwide

To reduce webcam child sex tourism worldwide, a Netherlands-based charity group has reportedly created a virtual 10-year-old girl, named Sweetie, who helps them identify paedophiles. According to reports, the members of the Terre des Hommes International Federation used computer modelling in order to capture the movements of a real person and then designed the virtual three-dimensional image of the girl. Reports say that the model is realistic enough for people to think that Sweetie is a girl from Philippines, sitting in front of a computer.

The group has reportedly also released a report along with a video, which shows their findings. According to the group's report, India came in at number three after the US and the UK, for the most chats done with Sweetie. There were apparently 103 users from the country. According to reports, the information collected by the team has been sent to the Interpol, including the images and videos.

A Neurocam that can read your mind

According to report, a device, known as Neurocam, can read people's mind by recording footage from the user's own point of view. The device has EEG sensors, which can scan the user's brain activity. This recognises the spikes in the user's interest, based on a measuring system.

The device has a mechanism, which can hold an iPhone strapped to the side of the user's head. Further, there is a prism fitted, which allows the smartphone's camera to record footage from the user's point of view. The iPhone app for Neurocam marks the spikes in interest from one to 100. If the spike is marked 60 or above, the smartphone automatically starts recording footage of whatever the user is looking at. The

StarChase GPS bullet and StarChase (inset)

footage that is recorded comes as GIFs, which lasts for five seconds.

A GPS bullet that can track vehicles

A bullet shot at a vehicle does not always have to be lethal. A new kind of bullet, called StarChase, has been designed to track vehicles and not damage them. According to a *Geeky Gadgets* report, the bullet is as big as a small artillery shell and, instead of using gunpowder, it is fired using pressurised air.

Further, being this big, the bullet obviously is not shot from a gun. Instead, the StarChase bullet is shot from a vehicle-mounted launcher, which is fitted on the top of a police car's front bumper, said the report. The launcher comes in both single-barreled and double-barreled variants.

Electronic tattoo that can take calls

It may sound like a Hollywood sci-fi but a phone company is reportedly working on an electronic tattoo, which will serve as a transceiver for smartphones. In this technology, the receiver and microphone of a smartphone are tattooed on the user's skin and can then become a wearable device, which

connects with smartphones and tablets.

According to reports, the Google-owned Motorola has filed a patent for making the tattoo. The patent reportedly states that the tattoo is inked on a person's neck and will reportedly send information using Bluetooth, Zigbee or NFC connections. Further, the electronic tattoo apparently takes the sounds and vibrations from a person's throat, which does away with the background noises that may or may not be present. The tattoo apparently also has a display along with user interface, which can allow users to input commands.

Idea of merging man with machine comes one step closer

Coming one step closer to manufacture of devices that can be integrated with the human body, Tim Cannon, a biohacker from Germany, has implanted a chip on his forearm without anaesthesia.

According to the *International Business Times*, Cannon has reportedly implanted a big chip without anaesthesia. The video had been posted to YouTube and went viral receiving 169,987 hits when this story was posted earlier this month.

The video shows the entire procedure, beginning with the cutting of the
