

conditioning embedded in it. This application has immense usage in emergency situations, low-income and commercial housing.

The World Wide Web for robots

Engineers and researchers at Eindhoven University of Technology, Netherlands have developed RoboEarth, or simply put, the World Wide Web for robots.

RoboEarth is a huge network and database that lets robots share data with each other and learn from each other's behaviour. It stores knowledge generated by humans and robots in a machine-readable format.

Data stored in the RoboEarth knowledge base include software components, maps for navigation, task knowledge and object recognition models, making powerful computation available to robots.

Now, a brain-like chip

2014 is going to take technology to an all new level. A chip has been released that claims to work like human brain. Yes, you read it correct! Scientists have created a chip that will help computers mimic human brains. That is not all. The chip will also make the computer learn from its own mistakes.

Interesting? Here is more! The newly designed chip is capable of connecting with wires and mimicking biological synapses. Fitted with these chips, the new-age computers will be able to beat as well as tolerate errors. These chips are touted to make the term 'computer crash obsolete.'

Larry Smarr, an astrophysicist who directs the California Institute for Telecommunications and Information Technology, one of many research centres devoted to developing these new kinds of computer circuits, says, "We are moving from engineering computing systems to something that has many of the characteristics of biological computing."

With eyeLock Myris, even passwords lie in the 'eyes' of the beholder

Stemming from the necessity of developing newer, more sophisticated authentication mechanisms that are very hard to crack, EyeLock in association with Voxx Electronics has developed Myris, an iris scanner, which does the job

eyeLock Myris, an iris scanner
