

3D Video Projectors

3D video projectors provide a better 3D experience than 3D LCD and plasma TVs. Find out what's available and how you should make a choice

S. AADEETYA

There was a time when projectors were seen only in cinema halls, where they were used to show movies to a large audience. Now there are projectors that can basically be fitted in a home theatre, stage show, training centre, or a meeting room. One thing that has changed most with projectors is their technology and the cost.

But even today, projectors are not seen as a necessity at homes. However, these devices are gradually gaining penetration. Earlier, projectors were mostly associated with business/enterprise segment. One might not have imagined the cost of a projector coming down to the cost of a television set, but that is exactly what has happened. The prospect of watching movies with theatrical effect in the comfort of their own homes has surely caught the imagination of consumers.

The technology trivia

If you ask which is the best projector for your home, the answer is a 1080-pixel 3D projector. 3D projectors use single-chip technology like DLP and LCD, and require you to wear special glasses in order to watch the content in 3D.

3D projectors basically show two different images. In simple terms, the left eye always sees only the left image,

while the right eye sees the one on the right. These images are transmitted to the brain, where they get combined to result in a three-dimensional image. This technology is now available on affordable projectors from the likes of BenQ, Epson, Acer, Panasonic and ViewSonic among others.

Most 2D projectors are also capable of converting 2D content into 3D. That clearly helps the industry, which is looking to generate quality 3D content for its projectors.

Experts believe that 3D video projectors provide a better 3D experience than LCD and plasma TVs. This is because video projectors can display very large image sizes, providing a large field of view, which takes into account the viewer's peripheral vision.

"3D projectors use two overlapping images to give an impression of depth in the projection. One image is for the left eye and the other is for the right eye. Using special glasses, each eye sees a slightly different image, which increases the sense of depth," says Rajeev Singh, country head and CEO at BenQ India.

Market scenario

Projectors is a sunshine market in India, clocking a high growth of around 30 per cent per annum. Currently, the market size is 275,000 units with estimated revenue of 7.5 billion rupees.
