

MIT scientists develop battery-operated cheetah

Robots have always been seen as a support for defense, rescue and reconnaissance. Models are being worked upon for more than half a decade now and all have got energy from power cables. However, MIT has recently come up with a cheetah robot which has the same agility and speed like the real animal and operates on a battery such that it could be let free.

The revolutionary design was showcased at the International Conference on Robotics and Automation. The design was highly inspired by the animal kingdom and is of the same weight and size as the regular cheetah. The robot could run as fast and the design has totally imitated the Kevlar tendons on a cheetah's legs that help it gain speed and maintain agility.

Other running robots that the world has seen, such as the Boston Dynamics Cheetah funded by DARPA, use hydraulic power strides. However, MIT replaced it with a magnet synchronous motor that is permanent and is lighter than the previous counterpart.

World's first Wi-Fi router that does 40 Gbps even from 1 km distance

With so many data-hungry websites (and apps) surrounding us all through the day, a slow Internet connection is a bummer of sorts. Especially, if your wireless router does not allow you enough freedom to move and still have the same impact. So hold your breath as we tell you about a Wi-Fi router that can send a complete two-hour full-HD movie over a kilometre in less than a second!

Don't believe us? Well, researchers at the Karlsruhe Institute of Technology in Germany have managed to do exactly that. The hardware used to transmit the data at 240 GHz was cre-

Cheetah robot

ated by KIT and has a set of chips that is capable of sending high frequency signals. In this case, the higher the frequency, the smaller the antenna size to pick up the frequencies, which means faster transfer of data.

"The number of bits carried over the airwaves is in inverse proportion to that of the wavelength. This means, the shorter the wavelength, the more data can be transferred in a set period of time," reports the official site of the Institute.

Coming soon: Your mobile on your palm

You must have faced tough time when you forgot your smartphone back home and kept struggling throughout the day (or at last for hours). Well, as we all know that your hand is something you cannot leave back home (pun intended), researchers have developed a technology that literally puts the mobile phone on your palm.

Researcher Masatoshi Ishikawa along with his colleagues at the University of Tokyo has devised this innovative technology, which uses a unique camera, which is capable of combining high-speed vision and two rotational

mirrors. It then projects the device's display or keyboard onto your palm or any surface, allowing you to use it remotely from anywhere.

The high-speed vision allows the programme to track moving objects, so users would be free to walk with the phone image in palm, without the display ever shifting, ABC News reported. "You won't need a keyboard, you won't need to carry a smartphone, or a computer. You can make a call without anything," said Ishikawa, who expects to commercialise this technology in a year or two.

Here comes solar-charging screen for mobile

The multi-dimensional functionality of smartphone has made it impossible for users to trust their device with juice to last for even a day, and this has practically made chargers (or even USB cables) an integral part of a person's luggage. But how about if we tell you that you can place the phone in front of sun and let the nature do its magic?

Hard to believe, but this is exactly what a startup from France, SunPartner Group, hopes to offer to smartphone consumers across the globe via
