

peak efficiency of 43.6 per cent, as confirmed by the Fraunhofer ISE Calibration Laboratory. This measurement was achieved at a concentration level of 319 (319 suns). The new cell has demonstrated more than 43 per cent energy-generating efficiency over a concentration range between 250 and 500.

A printer that can print ten metres of solar cells in a minute

After the invention of solar panels and its cost efficiency, here comes the printer that can produce 10 metres (33-feet) of solar cells every single minute. The gigantic printer has created a new history among the wonders created through solar energy. A team from Australia has invented this huge printer, which is a great achievement for

science and technology.

The *Gizmodo* has reported that the working process of this wonder printer is not very complex either. According to the researchers, the printer can utilise only the existing technology of printers in order to embed the polymer cells in the thin plastic and steel sheets. The speed of print-

ing has been reported to be ten metres every single minute. The technique used for screen printing of an image is also used here. It can also be used to print images on T-shirts the same way as screen printing.

The particular category of cells used in it does not belong to the best genre. However, it is the type that promises to lend itself for use in case you need flexibility. It can be used for solar windows, tents and even bags. It is easy to be made and will be soon in demand.

New bionic eye technology for visually impaired

The Monash University at Melbourne is working on a bionic eye that will eventually help visually impaired individuals to be finally able to see the light of the world. This will be the first-of-its-kind wireless technology that would be accommodated with a computer processor being implanted in the brain that will help blind people to determine shapes and forms.

The technology works with map dotting with the help of specially designed sunglasses. The bionic eye will work via a glass-mounted camera and will send the dotted map via a wireless transmitter to the processor in the brain.

While, it wouldn't be a full-on visibility, the bionic eye, according to the researchers, will help the blind see shapes like the edges of tables, footpath and hurdles in a dot-matrix format. This will ensure better mobility and less risk of accidents.

Smart clothes that speak to mobile

It is time to welcome some exciting and futuristic wearable devices that will take us into the future. When we talk about wearable tech, Google Glass and smartwatches are the first names that come to your mind, but it seems the industry is not content with these gadgets and is working on smart clothes that apparently will be able to communicate with your mobile phones via sensors.

You might be wondering if such clothes have appeared straight out of Sci-Fi movies but that's not the case. A company called OMSignal has been working on a project to develop such clothes since 2011. The company made its first public announcement recently as they have received

GOLDCREST IS THE BEST

Specialist in SMPS Transformers, Common Mode Chokes and Inductors
Manufacturing Capacity of Over Million Pcs per month

GOLDCREST E-TECHNOLOGIES Pvt. Ltd.
26, Sundar Industrial Area, NTY Layout, Mysore Road,
Bangalore 560026. Mob.: 9449254119
Email: goldcrest100@gmail.com
