

pany is developing a smartwatch, to be called 'Galaxy Altius.'

Wondering what features will this new smartwatch have? Though there is no clear information on the specifications but it will surely have audio and video calling, will be able to sync with your mobile or tablet, take notes or even monitor health-related data.

Measure your pulse with camera

Technology knows no bounds! Fujitsu Laboratories has developed a technology that uses a smartphone's camera to measure your pulse in real time.

In recent years, there has been increasing awareness about the need to maintain the health of employees and senior citizens, raising the demand for new, more convenient ways for individuals to monitor and manage their health, anytime and anywhere.

Using this technology, a person's pulse can be measured in real time by the built-in camera or webcam in a PC, smartphone or tablet.

The technology detects a person's pulse by measuring variations in the brightness of the person's face thought to be caused by the flow of blood. It is based on the characteristic of hemoglobin in blood, which absorbs green light.

Chinese smartphone with 5000mAh battery

A Chinese hardware manufacturer is hoping to mass produce a phone with a revolutionary 5000mAh battery. The company, Ding Xuan, is thought to be aiming to eradicate the common problem of poor smartphone battery life by producing the most powerful battery ever to be used in a phone.

Currently, there are a few phones in the market that are considered to have a long battery life, owing to the size of the battery the devices possess. Samsung Galaxy Note 2, for example, comes with a 3100mAh cell, while another competitor, Motorola Droid Razr Maxx HD, has a 3300mAh battery.

The kind of battery power present

in the new, still unnamed, Chinese phone is more closely related to that found in tablets.

China's Baidu working on Google Glass-like device

Chinese search giant Baidu is reportedly working on a wearable device like the Google Glass, which is expected to be showcased at the Google I/O in May.

According to a TechCrunch report, the company is developing a wearable device, Baidu Eye, that could match the features of Google Glass.

Baidu Eye will run the Android-based OS, Baidu Yi, which the company offers to its users in the native market. The prototype has an LCD display that will project through a prism, voice-controlled image recognition, and even a bone-conduction earpiece technology similar to Google Glass.

3D printing machine to create artificial human tissue

Researchers at the Oxford University have recently created a substance by 3D printing that could be used to replace damaged human cells in the near future.

According to the lead author Prof. Hagan Bayley, the 3D printing machine follows a computer programmed

diagram, ejecting tens of thousands of individual droplets to a specified three-dimensional network, which builds the synthetic tissue.

The process uses water and lipid molecules to produce a product that functions in a similar manner to that of some cell membranes.

It is hoped, due to the similarity, that this newly created artificial tissue could be used to replace damaged human tissue, hypothetically spelling the end of certain types of cancer. A working version of the manufactured tissue could also be used to administer drugs into the body.

Smartphones with crack-proof sapphire screens

Smartphone screens that are scratch-resistant and don't crack when you drop them, wouldn't be a far-fetched dream in the near future! Thanks to sapphire—a material that is likely to become cheap enough to replace the iconic Corning Gorilla Glass in smartphone screens—your next smartphone screen could be scratch-resistant to the point of being unbreakable.

According to a report by MIT Technology Review, GT Advanced Technologies and many other companies are working on a method for making sapphire sheets much thinner than the

nearly millimeter-thick glass used now on mobile phones.

The report added, "GT is also cutting the cost of sapphire manufacturing by following the strategy that it used over the last several years to reduce the cost of making crystalline silicon for solar cells."

Other companies, including Rubicon Technologies in the United States, Monocrystal in Russia, and Sapphire Technology in South Korea, are also working on lowering the cost of sapphire. The lowering of cost hints at the large market awaiting these manufacturers.
