

Key Questions To Ask About Your Website

- ▶ Does it matter if your website has features that your competitors don't?
- ▶ Does the idea of new customers fit in your business plan?
- ▶ Would it help your business if you got enquiries from other cities and other countries?
- ▶ What is the cost of your (or your team's) time spent in managing a complex website?
- ▶ Where would you like your online showroom to be—somewhere mixed amongst millions of websites OR visible on a popular B2B marketplace?
- ▶ Does a marketplace visited monthly by 20,000 decision makers be a good marketplace for your business?
- ▶ How much would renting a showroom on Lamington Road or Lajpat Rai Market cost you? How does that compare with Rs 1500 per month that you would invest in eleB2B.com?

eleB2B.com

What is the biggest challenge to characterising PCBs for high speeds?

Traditionally, it's been done with a number of tools including network analysers and then time-domain reflectometry systems based on oscilloscopes. These are very powerful tools because you can measure impedances on controlled buses, but they are extremely fiddly to use and, not to mention, get accurate measurements out of.

Our team took the basic capabilities of our very high-speed sampling scopes and pulse generators and integrated all of them into an automated system. With the enhanced speed of getting the required parameters, we took a lot of the burden off the designers and allowed them to get the information they want much faster.

Now that we have Internet-enabled oscilloscopes, what are the security issues in test and measurement?

Well, these days, most of the oscilloscopes can be hooked up to the Internet. While that creates a lot of opportunities to be more creative, it also poses new challenges. I would say, network security for those instruments is really no different from the network security for a PC connected to the Internet. A related challenge is to protect these instruments from viruses or infections.

What kind of change do you see with the adoption of new 802.11ac wireless standard?

The 802.11ac will double both data rates and RF bandwidths for designers in this market. As a result, we expect to see increased demand for high-speed serial data test solutions, and oscilloscopes with bandwidths in the 10+ GHz range. We also believe that the modulation schemes used will make jitter measurements increasingly critical.

EDA on cloud has suddenly found a lot of interest in the electronics industry as EDA vendors try to move analyses to the cloud. Are T&M players looking forward to something similar?

We are very interested in the ability to compare simulation results and real-world measurement results. With the explosion of data, we see it becoming more challenging, but at the same time, more valuable. If you can navigate the challenges there, you can really shorten the design cycle, which is what a lot of T&M is all about.

How is the T&M world evolving in terms of ease of use?

I think there's always something interesting coming out in the T&M world. Test equipment are not only becoming faster and more powerful but also more intuitive. So designers are more likely to pick up a new instrument and understand it quickly. I also think that they are gaining more insight into the workings of the circuit because of the kinds of tools and intelligence that are built into the instrument. ●
