According to reports, the device, called Nymi, is a wireless wearable bracelet that confirms a person's identity through his heartbeat.

It confirms the person's identity independently and then shares the information with the required device, like a smartphone or tablet using Bluetooth. The device is a bracelet and needs to be put on the wrist. It has a metal sensor on the top, touching which with the other hand completes a circuit through which the device records the user's heartbeat signature. It takes about two minutes to calibrate at first, followed by a few seconds every day.

In addition, removing the device by force will break the authentication. It has also been fitted with a dedicated cryptography chip, which

lets only authorised apps and devices receive data from Nymi. Further, the chip also ensures that your identity can not be spoofed. Preorders for the device have started at \$79, while shipping will start in 2014.

Detect kidney damage using smartphone

As per a study published in *Lab on a Chip* journal, scientists have invented a portable device that can carry out kidney tests and convey the data via a smartphone attachment. The device can greatly minimise the need for frequent visits to a clinic for people suffering from diabetes and acute kidney conditions, according to researchers from University of California, Los Angeles (UCLA).

As stated on medicalnewstoday.com,

the device weighing 148 gm can be attached to the camera of a smartphone to analyse the amount of albumin present in a person's urine. According to the authors, "This automated albumin testing tool running on a smartphone could be useful for early diagnosis of kidney disease or for monitoring of chronic patients."

Smartphone solution for eye treatment

A team of doctors from the London School of Hygiene and Tropical Medicine have come up with a solution for eye treatment that is an innovative, low-cost smartphone solution.

The researchers, led by Dr Andrew

Dr Andrew Bastawrous' Eye-Phone for eye treatment

Bastawrous, have used the smartphone, which comes with an add-on lens that scans the retina and an application to record the data while researching in Kenya, which was the testing ground for the pilot project.

The technology called Eye-Phone, is very simple to use and cheap to boot. Each Eye-Phone costs a few hundred euros. The study titled 'Nakuru Eye Disease Cohort Study,' has already checked over 5000 Kenyan patients. It is hoped that it will one day revolutionise access to eye treatment for millions of low-income Africans who are suffering from various eye diseases and blindness. Bastawrous says his Eye-Phone has proved its worth, and can easily and accurately diagnose ailments including glaucoma, cataracts, myopia and long-sightedness.

Solar dryer to help prevent food wastage

Doctoral students Vaibhab Tidke and Shital Somany have designed a low-cost solar device that can store up to three tons of food every year for individual farmers with an aim to prevent food wastage. The device is called the solar conduction dryer and comes with the ability to provide cold food storage more widely than affordable today.

Novel app for long-distance lovers

Now, sleep listening to your lover's heartbeats even if they are miles away. Yes you heard it right, researchers have recently developed a new app, Pillow Talk, that will let long-distance lovers listen to each others' heartbeats. It is a package of a wristband which picks up your heartbeats and transmits it via Bluetooth to the iOS or Android app.

3D printed skimmers used for stealing

A recent report from Australia reveals that a gang of criminals from Romania are using the 3D printing technology to steal from ATMs. They have combined computer aided design (CAD) skills to create a natural looking reader casing that fits exactly as a real one in an ATM.
