

The Future of High Resolution

Tom Coughlin is senior IEEE member

Today's viewers watch a variety of different video content on a number of devices. With the proliferation of mobile devices, we continue to push boundaries of how we view content, specifically in video quality. In fact, the recent introduction of 4K tablet computers and an iMac computer with a 5K retina display is an indication of interest in high-resolution images, even in smaller-screen environments. With the introduction of these higher-resolution formats for a variety of devices, are we at the point or will we ever get to a place where our vision deems all these extra pixels unnecessary?

Picture perfect: The case for pixels

All of the heavy-hitting technology companies have one thing in common when releasing new devices—resolution, which is a focal point as one of the selling features. And why should it not be? One of

the main attractions of laptops and mobile devices is for entertainment purposes, such as watching shows or movies on Netflix.

As a result, video streaming has become a standard activity for consumers. For example, within the last couple of years, the concept of TV Everywhere has exploded. This has caused service providers to upgrade network capabilities to offer the best possible viewing experience for their customers. High-definition viewing is no longer a benefit but a standard for consumers.

Higher-resolution content may be useful in smaller screens where a user may expand the viewed content to see smaller features. Thus, high-resolution content can lead to new games and other entertainment experiences where small features may be important. This feature is also valuable for amateur and professional video makers and for who may need to make modifications to images close to the pixel level.
