all files related to Microsoft Office will work in an environment that your OS will provide. This is how an

OS works in general. FreeRTOS is the same but with real-time execution ability.

When you talk about Windows or Linux, these OSes have a larger size and cannot be used with an MCU that is just a few microns in size. But with a size of only 4kB, FreeRTOS allows small components like MCUs to have add-on components for functionalities such as networking stacks and command-console interface.

The most important thing in any OS is its scheduler, which decides the time of execution of any application or program. Like, in the case of Windows on a desktop, the main work of a scheduler is to ensure that the desktop does not stop responding to its users, whereas in the case of Unix based multi-user OS, a scheduler ensures that each user gets the required amount of processing time.

In FreeRTOS, the scheduler follows a prescribed execution pattern, where each task is assigned a priority for execution.
