Are You In Suspense?

Are you wondering what happened to your order or payment, even after a fortnight? But did you mention your name and address clearly while sending payment, and what the payment was for?

We get several payments every month without adequate instructions or even identity of the person sending the payment. As a result we are unable to take appropriate action on these, till we get a complaint - if at all.

At EFY, we want you to be our satisfied customer. So please do let us know in case your payment or instructions are not even acknowledged within a fortnight. We are not that lazy!

Sample use-case scenarios for Sonic Visualiser

1. Create perfect sound clips for your Power Point presentation.
2. Become a detective and make a forensic discovery.
3. Boost old audio files that could be on their way to lost space.
4. Create a voice-recognition system.
5. Play some of the most-common audio formats (such as WAV, MP3, AIFF, AVR, FLAC, OGG and RAW) as well as less-popular file types (AU, CAF, HTK, IFF, MAR, MPC, PVR, RF64, SDS, W64, WVE and XI). Import and overlay annotation layers (CSV, LAB, MID and TXT) on top of waveform representations. Use plugins to automatically calculate annotations, taking into account tuning and sound pitch.

making the experience smooth. As the wave progresses, various frequencies can be connected by lines, steps or blocks.

A spectrum can be considered a vertical slice of a spectrogram (a spectrogram describes the change in frequency over time). Brightness or colour of pixels indicates the phase changes. An online course explains a spectrogram thus, "Speech is a continuous flow: phones are not discrete or distinct from each other, but these merge into one another, and spectrograms assess and visualise this continuity."

Both of these visualisations allow us to change the scale and range of the signal in display. We can even observe waveforms in different colours according to frequency. A very useful colour-rotation feature for sudden transitions helps isolate areas with similar signal levels. To obtain the spectrum or spectrogram, a series of Fourier transforms have to be applied to the signals. We can set window size for a frequency-time balance, fix window overlap to decide the proportion of overlap and select window

While viewing an audio tone as an electrical signal, there is the advantage of knowing where what is happening and process it to make the signals more pleasing

shape from a list of Hamming, Hann (also known as Hanning), Blackman, Blackman-Harris and Nuttall (cosine based windows), Gaussian, Parzen, triangular and un-windowed (rectangular) options. Hann window is the default and should be appropriate for most purposes.

A few layers for handy viewing

For perfect time analysis of the signal, we can add vertical lines corresponding to a given time instant, label instants, display points differently, connect these via lines/curves or even segment regions. A note layer that helps group points as notes, a region layer to apply a particular operation on just a section of the signal and a text-and-image layer are also present.

Often, harmonic notes lead to confusion in audio analysis, and to help with this, this tool offers a harmonic scale to pinpoint respective signal frequencies. There is also a colour 3D-plot option for signals that have groups of frequencies at different time instants, with each group having its own value. The plot is not editable and appears only when a transform
