The Internet of Things (IoT) is fast making its presence felt in all walks of life—right from an operation theatre to a home theatre set-up. But with all the worry about security and power issues, no one wants their devices to be connected to everything 24/7. This story on innovation is about one such device that comes to life only when you trigger it. It wakes up from slumber, connects to the Internet, does the job assigned to it and lets you know with its multi-colour light emitting diode about the outcome. Once done, it goes back to rest. How do you trigger it? Just by pressing one button!

1btn, or One Button, as the name suggests, is a button powerful enough to trigger a multitude of actions. It could be to send an email, a text message, post a tweet or even invoke a remote server script. The latter, say the innovators, is the most powerful thing 1btn can do, as it ultimately passes on full control into your hands, a delight to hackers and makers. 1btn comes packed with tremendous

potential to control anything connected to the Internet, literally!

Be at your creative best and customise your button

Have you watched the Amazon dash button advertisement? 1btn is an advanced version of the same, with extended capabilities and the first in the Indian market. A scalable and programmable version, its interface is Web based and does not rely on a smartphone, although it could work with one. 1btn can be configured multiple times in the console to make it perform different actions at different time slots.

You can now execute your plan for a king-size lifestyle. You wake up in the morning and a press of the button turns on the coffee maker and the geyser. A push in the next hour opens your garage door and locks your house safely. An action before lunch time orders your favourite dish from your daily restaurant and even calls a cab to deliver it to you.

Send out a meeting alert to everyone on the floor, get your kids to push the button to let you know they reached home safe, or even send a message to your parents to remind them to take their tablets. Use it to control your stopwatch for workouts or connect to If This Then That (IFTTT) service using Maker Channel and let it command the Internet for you. The possibilities are enormous. You just need to write your code and pressing the button kicks it off.

Why not use a smartphone instead

1btn being just a button is typically designed for a single task. It is the simplest user interface for single-

*Putting together
the neat package*
