

SIMPLE TRAFFIC LIGHT SYSTEM

■ ANIRUDDH KUMAR SHARMA

Traffic lights are used at road intersections to control vehicular traffic without traffic policemen. These allow orderly and uninterrupted movement of vehicles during peak hours.

Generally, a traffic signal system has three lights and is run by a microcontroller. The green light on the bottom of the light stack signals the traffic to proceed, the orange light in the middle warns the traffic to slow down and prepare to stop, and the red light on the top signals the traffic to stop.

Traditionally, traffic lights use bulbs, which consume a lot of power.

Here we present an adaptive traffic light system that uses readily available components. As traffic lights are required throughout the day, LED lights have been used. These are more efficient and save energy.

Circuit description

Fig. 1 shows the circuit of the simple traffic light system. It is built
