letters in local languages. It can also be used to create webpages in your own mothertongue.

Program description

The indiscript.htm program has a text area that is used as the main window where the characters are printed. It has a combo-box in the top left corner of the window that, when selected, outputs the respective keypad for typing the text (see Fig. 1).

The program uses ASCII values for character display. The characters have been locked and cannot be copied to other applications like Word, Excel, PowerPoint, Notepad or Wordpad. Therefore the program has a separate screen for characters.

When a particular language is selected, it displays the respective language keypad as shown in Figs 2-10.

Testing steps

This program has some limitations. There is no separate *matra* key. For example, in order to type *tra* character in *Pavitra* using Devanagari script, you have to select 'Hindi' option in this program and then type *ta* and *halantha* followed by *ra* key. Since these are Unicode-based ASCII characters, you cannot assign them at one go. For the space bar function, place the mouse pointer near the text, click the mouse to make the cursor blink and then press the space bar from keypad.

The program was tested on a Windows XP machine with Service Pack 2. It also works well in Windows 7 operating system. Many systems have extended ASCII Unicode interface, which supports Indic language scripts. However, you may experience problem in display of Hindi, Malayalam and Gujarati fonts on a laptop running Windows Vista.
