interfaced with 'Runnable' to check file modification. The checkfilemodification() method checks any modification or change done in the code. The createbat() method in the JGuiDer.java file is used to create a compiler.bat file each time on execution. This compiler.bat file has the code for compiling, running, creating the jar file, registering the file type, etc.

'PopupMenuCreator()' in 'JGuiDer.java' helps to create the popup menu while right-clicking the mouse button inside 'JtextArea' of the editor (refer Fig. 2).

The Menucreator subclass inside the main JguiDer.class is used to create the main menu bars on the top of the editor screen. It includes menu items for all the functions of the editor. Almost all the buttons and menu items have separate 'ActionListeners' in 'JguiDer.class'. The icons for the menu items can be added as follows:

```
JMenuItem JOP = new JMenuItem
```

Fig. 8: Typical message display in build output window

Fig. 9: Example program output

Fig. 10: Jpackager window

```
("OptionPane", new ImageIcon  
getClass().getResourceLoader().  
getResource("pic/JGuiDer/opi.  
gif"));
```

The next important class is 'Tool-Barcreator' in 'JguiDer.class' that creates the toolbar. The toolbar includes buttons for important functions.

'OptionPane' under 'Tools' menu is created using the OptionPaneCreator.java file. It creates code for the JOptionPane interface (refer Figs 3 and 4). 'JOptionPane' makes it easy to pop up a standard dialogue box in your application that prompts users for input and output or display message.

The user tools can be used to manipulate any type of external file. For example, when you click 'Customise' button to import a '.jpg' file, a dialogue box opens (refer Figs 5 and 6). Browse the .jpg file and click 'User Tool 1' option followed by 'Save' button. Close the dialogue box and click the leftmost tool icon to open

the .jpg file on the editor screen.

Java project. The project section is used to create the Java projects so that you can create the executable jar file.

A project file can be created by clicking 'New Project' in the pop-up menu. After creating the project, you can add new classes by pressing 'CTRL+ALT+C' keys. The executable jar file for your project can be easily created by 'Create Jar' button under 'Tools' menu. While compiling the project (press F7 or click 'build' button), all the Java files in 'src' folder are compiled and classes folder is generated as the output.

Project settings. This dialogue box allows you to select the options for the main class and class

path of the project (refer Fig. 7). All the files inside 'src' folder are added to the 'Main-Class' combo box. You can choose the main class from there. The next is the jar file option. The names of the files inside the 'classes' directory and the relevant files to be included in the executable jar file are mentioned here. You can select the files by clicking 'Select' button in 'Project Setting' window. You need to click the corresponding check box either to include only class files or all the selected files. You can save data by clicking 'Finish' button or cancel by clicking 'x' button. The 'Class Path' field under 'Project Setting' dialogue box is used to set the directory of the package used.

Compiling and running. Both the single source and the project files can be compiled and run using 'Run' button in 'Build' menu. The processing information of the compiled file is displayed in 'Build Output' window
