

Simple GPIB Connectivity for Laptop & Desktop Computers

- Lightweight
- Compact Size & Desktop
- Ideal for Laptop Users
- Connectivity GPIB Instrument via USB

Compatible with Your Existing Programs

No Rewriting of program Code Necessary

- APIs compatible with the NI-488.2* driver software
- Fully compatible with IEEE 488 and industry-standard VISA
- No GPIB cable required
- USB 2.0 compatible
- Maximum GPIB transfer rates of more than 1.2 Mb/s

* NI is the trademark of National Instrument Inc.

Other Products.

- Data Acquisition
- cPCI / PXI Platform
- Embedded Computing
- Ampro by ADLINK Extreme Rugged Products
- Industrial Computers

Several technologies such as ZigBee, ultra wideband (UWB), Wi-Fi, Bluetooth and WirelessHART are contending to rule the industrial automation space, while standards such as the ISA100 are attempting to streamline things

software platforms and open systems in industrial automation have made it possible to integrate different control disciplines into a single platform.

The possibility of combining things like PLCs, robots, computer numeric controllers (CNCs), human-machine interfaces (HMIs) and vision systems from different manufacturers onto a single platform allows users to exercise their judgement and choose just the right mix of control disciplines for every application. Plus, the user has the flexibility of upgrading, replacing or scaling up just some of the components at a time and not all. He can reorganise the devices to work in different ways. In such and many other ways, integration enables better asset management and flexibility as well.

Advanced software engineering has been one of the main enablers of such integration. Web services, data access specifications, service-oriented architecture, composite application frameworks, workflow engines and application integration have made

Networking, standards, convergence of communication technologies, powerful software platforms and open systems in industrial automation have made it possible to integrate different control disciplines into a single platform

information and control flow possible between industrial automation systems and other enterprise systems. At a very basic level, all these technologies enable disparate applications to share information and instructions with each other, by using a common standard/language that all of them can understand at the interface.

This enables integration at various levels—machines can be strung together into a seamless workflow, the plant automation system can be fit into the entire product lifecycle, the product (from design to manufacture) can be integrated into the business, and the business itself can be linked to other businesses such as the suppliers' and OEMs'!

The result: a real-time enterprise

A real-time enterprise is one that is equipped to act on events as they happen. It is not a new concept, but a melange of several old concepts such as just-in-time inventories, enterprise resource planning, supply chain management, customer relationship management and more.

It is about getting information in and out quickly, monitoring the business as it happens, and making quick, effective, agile decisions. In the past, there existed a gap between the factory and other information systems that always stood in the way of implementing truly real-time enterprises.

Today, industrial automation and its league of smart devices, mobile and wireless technologies, M2M communications, pervasive computing and powerful software engineering have removed this disconnect by making the factory an integral part of the entire enterprise. What's more, beyond such integration, modern technologies have also made industrial automation systems accessible from anywhere using mobiles and PCs, literally encapsulating the whole enterprise into the employees' hands! ●
