

YOUR PC MAY BE UNDER CYBER ATTACKS!

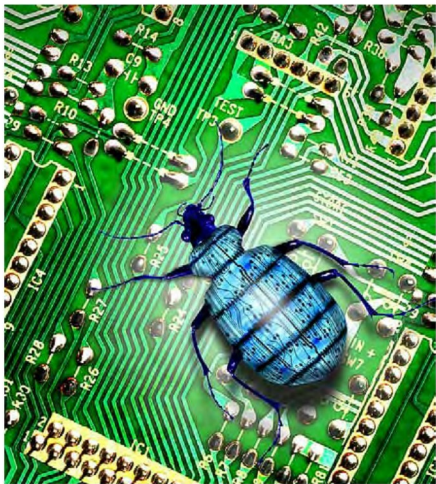

Virus attacks are what most of us worry about when it comes to protection of our computer system. But your system could be under attack by many other types of malicious codes that are no less harmful

■ TULARAM M. BANSOD

Most people think that just by installing antivirus software in their computer they can protect the computer. But it is a wrong notion. As you connect your computer to the Internet and open your favourite website, someone may be noticing that you are on the Internet. Some alien code may come and sit in your system. This code can be rootkits, stealth code, adware, spyware, worm or virus. I have mentioned viruses in the last because that's what most of us worry about. But what about the threats other than viruses and worms?

There are various layers of security for your computer. You need tools to protect all these layers—for physical security, people are putting access controls like biometric tools.

Rootkits is a group of programs that installs a Trojan login password through a back door, along with a packet sniffer. The sniffer is a program that secretly captures network packets of your computer and sends them to the owner of the sniffer. The sniffer program can capture your login information, thus giving to the hacker access to such information as user credentials. Here login.exe works as a Trojan file. Due to login.exe file, when you enter login details on your machine, Trojan program captures your legitimate login and sends it to the hacker. Now, the hacker can visit your computer as a legitimate user because he has become owner of your machine.

Stealth malware is a malicious application that is able to hide itself from system monitoring tools and even anti-virus software. We can say that rootkits are stealth malware. So when you purchase antivirus software, ask for software that will remove rootkits and stealth malware too.

Adware comes with free drivers. It is a program that gets installed on

your computer at the same time as a shareware or similar program; adware usually continues to generate advertising even when the user is not running the originally desired program. We cannot say that adware is malware, as it doesn't harm the computer but just annoys the user.

Spyware is any software that secretly gathers user information
