

contents by calling public IP address along with port 8081.

But the problem still remains—which computer's IP address should be entered on the browser page?

For that, find out the IP address of the modem or router obtained from the Internet service provider at that point of time. For that, go to the status page of router again and find out its external IP address (say, <http://a1.a2.a3.a4>). This is your public IP address.

Now, you can share this IP address along with the port number with your friend. He or she can enter this IP address plus port number on the browser to access your live-streaming video.

Note that, this IP address may undergo changes many times in a day, as most home connections have a dynamic public IP address. So

Author's old mobile phones connected to a laptop for live streaming

keep track of it before enabling port forwarding.

The easiest way to get an external IP is to use an old mobile with a SIM card along with an Internet pack, and go online. Run `ifconfig` at command prompt; you will get the external IP address for the laptop or Raspi.

The old mobile acts as a mo-

dem to get connected with the Internet for reverse traffic flow. Since the modem in the phone is primitive in nature, it has no firewall. When an old mobile is connected to the Internet it gets a public IP address (202.54.x.x or 132.56.x.x) unlike 192.168.x.x or 10.10.1.2.

In short, if your friend wants to access your live-streaming video through your computer, he or she can type, say, <http://a1.a2.a3.a4:8081> on the browser or VLC player of his or her computer or mobile phone. And you can talk on your old phone as you look at the live-streaming video on your computer. **EFY**
