

Digital Signals, Upgradability And UHD TV Driving **AUDIO-VISUAL TESTING**

Saurabh Durgopal
is working as
technology
journalist at EFY

Switching on a television set in the evenings is a habit for most. Surfing through the channels we may find a telecast we like and go on to watch. While there are no issues on most days, you might occasionally detect a noticeable difference in the audio and video. This could be the audio going faster than the video or lagging behind, or some other minor issue. It might not be a big issue for the end user sitting at home if it happens occasionally, but it definitely is a problem for the television broadcasting company. If this problem persists, their viewership could reduce and affect the revenues adversely. Hence efficient functioning of such systems is their necessity.

The biggest user of audio-video T&M equipment is the broadcast industry, with the largest share going to television due to its immense popularity. With the amount of reach and effect this industry has, it needs

nothing but the best in equipment.

Here we discuss T&M equipment for audio and video related tests, which includes signal generation and analysis tools for specific technologies, as well as equipment to test the audio and modulation quality of communication radio for security and military communication.

What to test for

Broadcasting of signals started in analogue form, but in this era we use combinations of analogue and digital modes of communication. Hence the testing parameters should cover both types of signals. The different tests to be performed include content server tests, reception tests, cable-antenna tests, Moving Picture Experts Group (MPEG) coder-decoder (Codec) tests, signal quality and signal condition tests, modem tests, intellectual property (IP) quality tests, etc.
