for this software. You can download the same from *www.python.org/downloads*

Once you open the link, you will see the page shown in Fig. 1. Click

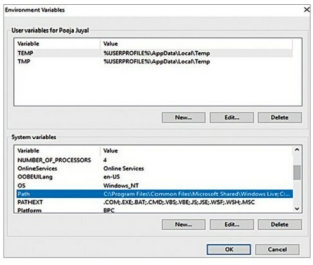

Fig. 9: Path under System Variables

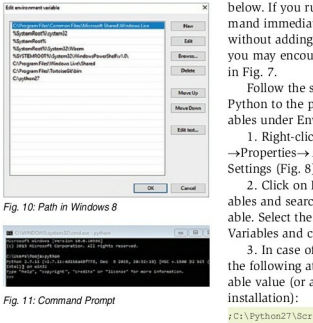

Fig. 10: Path in Windows 8

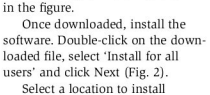

Fig. 11: Command Prompt

Download Python 2.7.11 as shown in the figure.

Once downloaded, install the software. Double-click on the downloaded file, select 'Install for all users' and click Next (Fig. 2).

Select a location to install Python. Click Next (Fig. 3). Keep the default selection and click Next (Fig. 4).

You will be prompted for permission to install the software; select Yes. The page shown in Fig. 5 will appear to show the status of installation. Once finished, Next tab gets activated.

Click Finish to complete software installation (Fig. 6).

Add Python to path environment variable

Python can be directly run through the Command Prompt on Windows machine. But this needs Python directories to be added in the path under System Variables as explained below. If you run python.exe command immediately after installation, without adding the path variable, you may encounter the error shown in Fig. 7.

Follow the steps below to add Python to the path in System Variables under Environment Variables:

1. Right-click on My Computer →Properties→ Advanced System Settings (Fig. 8).

2. Click on Environment Variables and search for the path variable. Select the path under System Variables and click Edit (Fig. 9).

3. In case of Windows 7, add the following at the end of variable value (or at the path of Python installation):

```
;C:\Python27\Scripts
```

4. In case of Windows 8 or above, the window shown in Fig. 10 will appear. Click New and add:

```
C:\Python27
```

5. Select OK and it is done.

6. Open Command Prompt and type Python (Fig. 11). This screen confirms proper installation of Python.

7. Now you can directly run Python commands from Command Prompt.

Prerequisites

Before you start writing your program, install required packages so
