

BINAY— Lighting Up The Future

Binay LED Aviation Obstruction Lights

BINAY LED-based MEDIUM INTENSITY
Aviation Obstruction Light Beacon

As per the International Civil Aviation Organisation (ICAO) requirements
for use on structures above 45m

Available in Low Intensity and Medium Intensity versions (as per
the International Civil Aviation Organization guidelines), BINAY's
patented LED Aviation Lights come with a 5-year warranty

LED Obstruction Lighting for:

- Industrial chimneys and smokestacks
- Transmission, microwave, and cellular towers
- Radio, TV and similar structural towers
- High-rise buildings and structures
- Airports and airfields

The BINAY LED Aviation Obstruction Light offers the following advantages:

- Fit-and-forget maintenance-free operation
- A long life of 100,000 hours (20 years at 12 hours daily burning)
- Pays for itself within a short period of operation in the form of reduced installation, maintenance and servicing costs
- Quick installation; Reliable operation 365 days per year
- Shock-proof and vibration-resistant
- Over-Designed Intensity to allow for natural LED intensity degradation over its operating lifetime

THE BINAY LED OBSTRUCTION LIGHT IS UNDER ACCEPTED
PATENT, AND AS SUCH IS A PROPRIETARY PRODUCT

manager dynamically assigns the chip's tasks to fault-free parts. The chips have many cores; each core performs sub-tasks of a more complex application. For instance, satellite navigation comprises many digital signal processing tasks. The run-time resource manager dynamically determines which core does what. Cores can swap tasks. It does not make a difference which core does what, so cores can take over the tasks from failing cores and the chip can repair itself, extending its longevity.

Optical-fibre transmission at 40 Gbps

A new laser technology revolutionises optical-fibre data transfer and communication by delivering error-free data at a record speed of 40 gigabits per second (Gbps). The technology is cheaper and more energy-efficient than its conventional versions, which can send only up to 10 Gbps through optical fibres.

Unlike a conventional laser, the light from a surface-emitting laser is emitted from the surface of the laser chip (not from the edge), like in an LED. The gain is the ability to not only fabricate but also test the lasers on the wafer (a 75mm wide substrate of semiconductor material) before it is cut into individual chips for assembly. The lasers work directly where they sit on the wafer. Conventional lasers work only after partition. The ability to test up to 100,000 lasers on a wafer reduces the cost of production to one-tenth compared with conventional lasers.

The laser volume is smaller, requiring less power without losing speed. The energy and power consumption is a tenth of what a conventional laser requires at 40 Gbps.

World's first life-search application

Don't remember who called you up while you were watching a movie in the cinema? Ask Friday, the world's first life-search application from Dextera.

The application automates the process of building a database by creating a semantic map of activities that the users do on their phone and also identifying the places they visit. This enables users to retrace activities and pinpoint the info they need. The database building process happens in real time and requires almost zero user input. Users can always enhance the map with extra info. To retrieve an information, they just have to ask a question via voice or text
