

LANGUAGE TRANSLATOR USING GOOGLE TRANSLATE AND VB.NET

■ SOMARAJ N.

It's amazing if we are able to translate a text to our favourite language. Google Translate makes this job easy. It is a free translation service available on Google website (<http://translate.google.com/>) that provides instant translations between different languages. It can translate words and sentences between any combination of the supported languages.

How does Google Translate work?

When Google Translate generates a translation, it looks for patterns in hundreds of millions of documents to help decide on a translation. By detecting patterns in documents that have already been translated by human translators, the translation service guesses as to what an appropriate translation should be. This process of seeking patterns in large amounts of text is called 'statistical machine translation.'

Since the translations are generated by machines, not all translations will be perfect. The more human-translated documents that Google Translate can analyse in a specific language, the better the translation quality will be. This is why translation accuracy will sometimes vary across languages.

Here we present Google Translate software using Visual Basic .NET 2005.
