

BINAY- Lighting Up The Future

Binay LED Aviation Obstruction Lights

BINAY LED-based MEDIUM INTENSITY Aviation Obstruction Light Beacon

(As per the International Civil Aviation Organization (ICAO) requirements for use on structures above 45m)

Available in Low Intensity and Medium Intensity versions (As per the International Civil Aviation Organization guidelines), BINAY's patented LED Aviation Lights come with a 5-year warranty

LED Obstruction Lighting for:

- Industrial chimneys and smokestacks
- Transmission, microwave, and cellular towers
- Radio, TV and similar structural towers
- High-rise buildings and structures
- Airports and airfields

The BINAY LED Aviation Obstruction Light offers the following advantages:

- Fit-and-forget maintenance-free operation
- A long life of 100,000 hours (50 years of 12 hours daily burning)
- Pays for itself within a short period of operation in the form of reduced installation, maintenance and working costs
- Quick installation; Multiple operation 365 days per year
- Shock-proof and vibration-resistant
- Over-Engineered Intensity to allow for natural LED luminosity degradation over its operating lifetime

**THE BINAY LED OBSTRUCTION LIGHT IS UNDER ACCEPTED
PATENT, AND AS SUCH IS A PROPRIETARY PRODUCT**

"This system collects very reliable and precise data. It is equipped with a very effective noise-filtering system, and has batteries that can last three-four weeks at a time," says EPFL professor David Atienza.

Eye-tracking computer interface for disabled

Luis Cruz, a 17-year-old electronics and programming whiz from Honduras, has created an Open Source eye-tracking computer interface that can be of great help for the disabled. The Eyeboard device enables users with motor disabilities to enter text in a computer with eye gestures rather than a physical interface.

The eye-tracking computer interface works on the principles of electro-oculography, that is, measuring the resting potential of the retina using electrodes placed just beside the eyes. As it turns out, the human eye is polarised – the front of the eye carries a positive charge and the rear has a group of negatively-charged nerves attached to the retina. So when the eye is moved, the electrodes can be used to measure the change in the dipole potential of the eye through the skin.

Though the system does not track eye movements with the accuracy of a high-tech contact lens or video tracking system, it is non-invasive as electrodes are mounted in a pair of sunglasses. A software takes the inputs and uses these to choose letters in a grid, so that users can type entire words using just their eye motions.

Electronic-focusing eyewear

PixelOptics claims to have developed the first electronic-focusing eyewear. A touch of the temple or tilt of the head activates a layer of liquid crystals in each lens, instantly

emPower! electronic-focusing eyewear

creating a near-focus zone. emPower! not only gives you control over your vision, it also provides wider fields of view and less distortion than progressives.

The technology used is similar to that used in LCD televisions. Each of the lenses in emPower! features a virtually invisible layer of liquid crystals that instantly adjusts and provides the user with a near-focus zone. The zones can be activated in two modes—manual and automatic. In manual mode, a touch of the temple triggers the near-focus zone, while another touch turns it off. A swipe of the temple activates the automatic mode, so the
