

VIDEO SURVEILLANCE SYSTEM THAT NEVER SLEEPS

The IP-based distributed video surveillance system from Silvan Innovation Labs is an intelligent security system that provides surveillance even in the face of power and network outages. Read on...

Smart IP surveillance concept

■ VANDANA SHARMA

"One is not exposed to danger who, even when in safety is always on their guard."

— Publilius Syrus (Roman author, 1st century B.C.)

With statistics related to crime and security breaches being on the rise, globally, use of video surveillance via analogue or IP-based cameras has become commonplace to counter these threats. Yet, there are times when these devices fail to deliver value, especially when the power or network connection either fails or is disabled by miscreants. In a country like India which lacks power and spectrum consistency, running the surveillance system through uninterrupted power supply (UPS) can also prove to be an expensive option.

But wouldn't it be great if you could deploy a surveillance system that works even in such odd situa-

tions? Silvan Innovation Labs' smart video surveillance system is one such solution that seemingly addresses many of the bottlenecks that can come in the way of ensuring 24x7 security of an organisation's premises or public places.

What makes it 'smart'?

The Silvan video surveillance system is an innovative mix of hardware, software and analytics that makes the system intelligent. A few features worth taking note of are embedded storage, distributed intelligence across network, optimisation to save power and image capture even in the dark.

Embedded storage. The system is a combination of cameras that are connected wirelessly through a Wi-Fi connection, thus forming a network. In-built power and storage capabilities make the cameras work and store events even when mains power fails.

Apart from this, one of the cam-

eras in this network even doubles as the 'master' camera and has an in-built storage capacity to serve as a network video recorder. It also collates the video images captured by other cameras in the network and streams them in a combined way to the visual medium, thus saving on the cost of buying an additional storage device to store the video footage. For some reason, if the master camera malfunctions and stops to work, the other cameras in the network reconfigure automatically and any of them assumes the role of the master camera storing and streaming the video coverage.

"The on-board memory for video capture and storage helps especially in brown-out conditions (when the network fades or gets disrupted) and forensic reconstruction of events in the case of any security breach," says Giri Krishna, CEO of Silvan Innovation Labs.

Distributed intelligence across network. The cameras are embedded with algorithms that make them capable of detecting a predefined set of events and generate alerts. This intelligence is distributed across the network of cameras, which means each camera can be programmed to detect a unique set of events and generate alerts. For example, a camera in a public place can be programmed to detect and raise an alert if anyone walks into that place with an object, leaves it behind and doesn't come back within a predefined stipulated time period to claim it. So when all the cameras in a network work in tandem, they are capable of generating alerts for a range of predefined instances that may lead to security breach.
