

DISPLAY INNOVATIONS PROMISING BRIGHTER FUTURE

Improvements in optics, digital signal processing, nanotechnology, materials science and chip design are fuelling the development of thin, light, energy-efficient, high-definition, 3D, multi-touch, interactive, flexible displays and more! These, in turn, are enabling the making of better televisions, mobile phones, sign boards and so on, slowly taking us towards the ubiquitous computing dream

Multi-touch water effect screening

Input, output and other peripheral technologies can make or break innovations. For example, no matter how small a chip becomes, a computer or mobile

phone cannot become smaller unless its display too becomes more compact. Similarly, however powerful a graphic processor is, its skills cannot be manifested in a device unless the display cooperates. Nanotechnology, three-dimensional (3D) integrated circuits,

solar-powered electronics, low-power devices or whatever be the next revolution in electronics, it cannot take off without the help from the display space.

There is a lot happening both in terms of the enabling technologies and the resulting experiences. Micro-
