

ponents and is embeddable in applications written in other languages (C/C++, Java and so on). It is also possible to add new modules to Python, extending its core vocabulary.

Some advantageous of Python programming language are listed below:

Readability. Python's syntax is clear and readable.

Good support. The Python community always provides support to Python users. Python code is freely available for everyone.

Easy to learn. The language is very easy to learn because its source code resembles pseudo code. It doesn't require long lines of code.

Fast to code. Python provides fast feedback in several ways. The programmer can skip many tasks compared to other languages. Thus it reduces both the cost of program maintenance and the development time.

The interactive interpreter that comes with the Python distribution brings rapid development strategies to

your project. Unlike the traditional programming languages that require several distinct phases (such as compiling, testing and running) and other scripting languages that require you to edit the code outside the execution environment, Python is a ready-to-run language.

Portability. Besides running on multiple systems, Python has the same interface on multiple platforms. Its design isn't attached to a specific operating system because it is written in portable ANSI C. That means you can write a Python program on a Mac, test it using a Linux environment and upload it to a Windows server.

Object-oriented programming (OOP). Python, as in Smalltalk, is designed to be object-oriented. Some of the implemented OOP functionality in Python is inheritance and polymorphism.

XMPP

XMPP is an open-standard communications protocol for message-oriented middleware based on eXtensible

Markup Language (XML). The protocol was originally named Jabber, and developed by the Jabber Open Source community in 1999 originally for near-real-time, extensible instant messaging (IM), presence information and contact list maintenance. Designed to be extensible, the protocol today also finds application in voice-over-Internet protocol and file transfer signaling.

Unlike most instant messaging protocols, XMPP uses an open system's approach of development and application, by which anyone may implement an XMPP service and interoperate with other organisations' implementations. The software implementation and many client applications are distributed as free and Open Source software.

PyAIML

PyAIML is an interpreter for AIML (Artificial Intelligence Markup Language) implemented as a standard Python package. It generates a 'brn' file, and hence called PyAIML's brain. This
