

BINAY- Lighting Up The Future

Binay LED Aviation Obstruction Lights

BINAY LED-based MEDIUM INTENSITY Aviation Obstruction Light Beacon

As per the International Civil Aviation Organisation (ICAO) requirements for use on structures above 45m

Available in Low Intensity and Medium Intensity versions (as per the International Civil Aviation Organization guidelines), BINAY's patented LED Aviation Lights come with a 5-year warranty

LED Obstruction Lighting for:

- Industrial chimneys and smokestacks
- Transmission, microwave, and cellular towers
- Radio, TV and similar structural towers
- High-rise buildings and structures
- Airports and airfields

The BINAY LED Aviation Obstruction Light offers the following advantages:

- Fit-and-forget maintenance-free operation
- A long life of 100,000 hours (20 years at 12 hours daily burning)
- Pays for itself within a short period of operation in the form of reduced installation, maintenance and servicing costs
- Quick installation; Reliable operation 365 days per year
- Shock-proof and vibration-resistant
- Over-Designed Intensity to allow for natural LED intensity degradation over its operating lifetime

THE BINAY LED OBSTRUCTION LIGHT IS UNDER ACCEPTED
PATENT, AND AS SUCH IS A PROPRIETARY PRODUCT

Robot brain implanted in a rodent

With a new cutting-edge technology aimed at providing amputees with robotic limbs, a Tel Aviv University (TAU) researcher has successfully implanted a robotic cerebellum into the skull of a rodent with brain damage, restoring its capacity for movement.

The cerebellum is responsible for coordinating movement. When wired to the brain, the robo-cerebellum receives, interprets and transmits sensory information from the brain stem, facilitating communication between the brain and the body. To test this robotic interface between the body and the brain, the researchers taught a brain-damaged rat to blink whenever they sounded a particular tone. The rat could perform the behaviour only when its robotic cerebellum was functional.

The chip is designed to mimic natural neuronal activity. "It's a proof of the concept that we can record information from the brain, analyse it in a way similar to the biological network, and then return it to the brain," said Prof. Matti Mintz of TAU's Department of Psychology.

Wearable depth-sensing projection system

The OmniTouch wearable projection system developed by researchers at Microsoft Research and Carnegie Mellon University enables users to turn pads of paper, walls or even their own hands, arms and legs into graphical, interactive surfaces.

The shoulder-worn system employs a depth-sensing camera, similar to the Microsoft Kinect, to track the user's fingers on everyday surfaces. This allows users to control interactive applications by tapping or dragging their fingers—much as they would with touchscreens found on smartphones or tablet computers.

OmniTouch

The projector can superimpose keyboards, keypads and other controls onto any surface, automatically adjusting for the shape and orientation of the surface to minimise distortion of the projected images. The palm of the hand could be used as a phone keypad or as a tablet for jotting down brief notes. Maps projected onto a wall could be panned and zoomed with the same finger motions as with a conventional multitouch screen.

'Electron superhighway' to quantum computers

Rice University physicists have created a tiny electron superhighway that could be useful for building a quantum computer—a new type of computer that will use quantum particles in place of digital transistors found in today's microchips.

The tiny device made from commercial-grade semiconduc-
